

ABSTRACT OF THE DISCLOSURE

The aim of the invention is fasten a riding ring of a rotary cylinder, particularly of a rotary kiln, whereby the riding ring, apart from the arresting thereof in an axial direction, can also be arrested in its peripheral direction with regard to the rotary cylinder casing without the manufacturing of the riding ring requiring complicated machine processes such as shaving, shaping, the making of through holes, etc. To this end, the invention provides that the riding ring is manufactured only in the form of a turned part, and clamping elements are placed around the riding ring periphery in a distributed manner. Said clamping elements engage in a non-positive manner with peripheral slots of the riding ring and are actively connected to supporting elements that are fastened to the rotary cylinder casing.
